Richard L. Epstein received his B.A. summa cum laude at the University of Pennsylvania and his Ph.D. at the University of California, Berkeley. He held a postdoctoral fellowship in mathematics and philosophy at Victoria University of Wellington, New Zealand, before an extensive career teaching mathematics and philosophy. He has been a Fulbright Scholar to Brazil and a National Academy of Sciences Scholar to Poland. He also owned and managed the Dog & Duck Coffee House. He is the author of the series of research texts THE SEMANTIC FOUNDATIONS OF LOGIC as well as CRITICAL THINKING and FIVE WAYS OF SAYING "THEREFORE". Currently he is head of the Advanced Reasoning Forum in Socorro, New Mexico. Walter A. Carnielli received his Ph.D. at the State University of Campinas, Brazil. He held a postdoctoral fellowship in mathematics and logic at the University of California, Berkeley, and is currently Professor of Logic and Foundations of Mathematics at the Department of Philosophy of the State University of Campinas, with almost a hundred publications in many-valued logics, paraconsistent logics, combination of logics and combinatorics. He has also been an Alexander von Humboldt Scholar to Germany (Munster and Bonn). Currently he is the Director of the Centre for Logic, Epistemology and the History of

Science of the State University of Campinas. Carnielli is the Laureate for Mathematics of the Telesio Galilei Academy of Science for 2013. --This text refers to an out of print or unavailable edition of this title.

Good.

Excellent!

This book is half mathematics and half discussion. Parts 2 & 3 cover the material for an integrated, introductory course in computability theory and logic (the primitive recursive functions, mu-recursive functions and Turing machines and their equivalence, first-order logic, some formal number theory, and Gödel's first and second incompleteness theorems). Parts 1 & 4 are given to philosophical discussion and (to a lesser extent) historical background. The longest chapters are one examining Church's thesis and one on intuitionist/constructivist views of mathematics. Overall the book is clearly written and well organized, and it contains interesting selections from the writings of prominent figures in the foundations of mathematics throughout. Adjoined to the end is a 25 page timeline, surveying 1834-1970. This is quite neat, but I wish it had been longer. The book should be useful both to people new to computability & logic, as well as those with some previous background, but the target audience is probably those with an interest in philosophy of mathematics. 1) Beginners- Its helpful to learn computability theory and logic together. But that's a lot of ground for a single volume to cover, and since this one is particularly short (parts 2&3 run only 157 pages), some of the material is only loosely sketched. I'd recommend a more thorough, grind-the-gory-details book as a central text and that you use Epstein & Carnielli as a supplement, providing a clean overview of what's going on. The philosophical material will either illuminate the motivation for the mathematical constructions, or will just muddy the waters for you, depending on your temperament. This can be skipped or skimmed if you want, but that would defeat the unity and aesthetic of the book. Be warned some of the historical writings will be hard for a beginner, especially as E&C don't take enough time to set the stage for them. 2) More experienced readers will enjoy the selections from Hilbert, Gödel, Turing, Post, Brouwer and others. These aren't the complete papers (see Davis or van Heijenoort for those), just choice passages. I enjoyed the amount of philosophical material included- more than your usual math book, but short enough to keep from getting tedious or slipping into general philosophy. Parts 2&3 form a succinct review of the basics if you need to brush up.

My five star review is relative to the chapters on primitive recursion and the Grzegorczyk Hierarchy. I haven't read the other sections. Grzegorczyk's Hierarchy is an early result in complexity theory, which defines classes of functions based on the primitive recursive functions. This class is smaller than the class of functions computable by a Turing Machine and hence is theoretically less interesting to most complexity theorists. It's not easy to find these results described in detail. I advocate making the details available for a number reasons. 1. Despite the sparseness of this class of functions, most programming tasks will wind up here. 2. A wide assortment of everyday mathematical functions can be defined recursively -- e.g. deduction -- so the pr functions are not theoretically vapid. 3. G's hierarchy describes the very nice structure of this versatile, but limited, class of functions, which can aid problem solving where applicable. 4. Some useful programming languages restrict themselves to the expressive power of the pr functions. 5. The machinery of pr functions looks very similar to Kleene's class (a historical successor of pr functions), which is equivalent to Turing's characterization. 6. Proof theory. Most texts unjustly don't even mention this class, much less give the full details, so I was very happy to see that it was covered in this introductory text. But the coverage is striking in its clarity. The pr functions are a very intuitive class of functions and this book treats them as such. I love the pace of this text, which is explicit, but not long winded. The exercises too build the reader's knowledge in an even fashion, with the obvious goal of giving a clear picture. Hand waving is avoided around Ackermann's function -- so rare to see! This book is a hidden gem with respect to the obscure topic of pr complexity.

this book takes you into the world of basic pure math. it covers the basic elements of math such as sets, functions, and proofs. but what is really making this book great and far apart from other similar books is its elaboration of recursive function and computability, and i find it interesting.
